

3v solar light control chip

Overview

Inside most solar-powered garden lights is an ingenious little circuit comprising a rechargeable battery, solar cell, inductor, LED and a little IC that does all the magic:

1. when voltage is detected from the solar cell, the LED is off and the battery will charge
2. as the solar cell voltage drops off (gets dark), the chip runs a boost converter to drive the LED load. According to the QX5252 datasheet, indicative values are as follows for a. When the voltage generated by the solar cell falls below about 0.2V, the boost converter switches on. Here's the waveform of the. I've followed the typical application schematic from the datasheet: the circuit simply connects the solar cell and battery to their respective pins.

YX8018 solar led light

The way that IC works is to use the solar cell both to charge the battery and sense darkness. The output of the solar cell is on the CE (Chip Enable) pin which must be pulled low to turn on the chip. As long as there is enough light to keep the pin at logical high, the solar cell is connected to ground and has a path to charge the battery.
