

# Can phosphoric acid be used to make new energy batteries

## Overview

Although global phosphate reserves stand at 72 billion metric tons, EV batteries typically require high-purity phosphate found in rare igneous rock phosphate deposits. In this infographic sponsored by First Phosph. Phosphate exists in both sedimentary and igneous rock types. Sedimentary rock forms from layers of sediment and organic matter, while igneous rock originates from cooled magma. The lion's share of phosphate reserves, around 70%, is located in Morocco. Significant igneous phosphate deposits are only found in Brazil, Canada, Finland, Russia, and South Africa. The igneous rock type itself is crucial, especially when considering the waste produced during the creation of purified phosphoric acid used in lithium iron phosphate (LFP). With a rare igneous anorthosite rock deposit in Québec, First Phosphate is leading the charge in producing the highest purity, ESG-driven, carbon-neutral phosphate for the future.
